Objective

Abnormalities of fetal growth are more common in twins. We introduce the growth curves for monitoring fetal growth in twin pregnancies in Slovenia.

Methods

Slovenian National Perinatal Information System for the 2002 - 2010 period was used to calculate birth weight centiles for all live - born twins between 22nd and 40th week of gestation.

Results

The calculated centiles of birthweight for all live - born twins in Slovenia served as the basis for drawing 'growth' curves.

Conclusion

The calculated growth curves for twins will help in the accurate diagnosis of small or large for their gestational age twin fetuses in the native central European population.
