Objective
Intra-abdominal fetal cysts are a rare finding, which is usually observed incidentally on routine anatomy ultrasound. There are no clear guidelines or criteria for follow-up and delivery in those cases.

Methods
In this paper we are presenting a very rare (as only fifty cases reported worldwide) series of twelve cases of fetal abdominal cystic lesions detected during routine anatomy scan and we will discuss the indication for early delivery in cases of abnormal fetal intestines. These cases were collected between 2014 and 2017. Cases were discussed separately and in detail in the fetal treatment unit at King Saud Medical City in Riyadh, most of them decided for conservative management, delivery for obstetric indications and for postnatal evaluation.

Results
After delivery, the diagnosis was confirmed (ovarian cysts 6/12, localized intestinal dilatation 2/12, mesenteric cyst 2/12, intestinal cystic hygroma 1/12, hydrometrocolpus 1/12). All the cases were treated surgically without morbidity or mortality.

Conclusion
We conclude that intraabdominal fetal cystic lesions can be managed conservatively and the intestinal dilatation can be managed safely and effectively by surgery after delivery, even with ultrasound findings of intestinal obstruction.
