

## A case of uterine wall defect in scar area after previous caesarean section

Maděrková Tozzi M, Lubušký M, Pilka R  
University Hospital Olomouc, Olomouc, Czechia

### Objective

A patient from the Center of An Assist Reproduction was sent to our clinic. She was a 44-year-old patient, one Caesarean section in 2010, after three unsuccessful attempts at embryo transfer where a scar defect was found during ultrasound examination. The patient complained about post-menstrual spotting.

### Methods

In the ultrasound examination with a vaginal probe, a triangular, spherical hypoechogenic resistance at the site of the predicted scar was displayed in the sagittal section.

### Results

Consideration of criteria for the surgical treatment method. The defect was treated with a hysteroscopic method in combination with subsequent laparoscopy.

### Conclusion

In the case of the above-mentioned difficulties, include scar syndrome in the differential diagnosis after a previous Caesarean section. Consider whether or not to resect tissue defect in surgical treatment.
