How should IVF babies be delivered?
Stefanija A. Jovanovska, Livrina V
University Clinic for Obstetrics and Gynecology Medical Faculty-Skopje. Ss. Cyril and Methodius University of Skopje, Republic of North Macedonia, Skopje, FYROM

Objective
The objective of this study is to examine the obstetrics outcome in patients conceived by IVF. Is there are difference in outcome depends of the mode of delivery?.

Methods
Retrospective study on a total of 4630 patients hospitalized and delivered during 2018 at the university clinic for obstetrics and gynecology.

Results
During 2018 we recorded a total of 5565 deliveries at our institution, from which IVF pregnancies were 106 (2.28%). From the total number of patients 34.75% were delivered by a cesarean section. Importantly 4.86% were pregnancies conceived by in vitro fertilization and embryo transfer-Almost half of them were premature (gestational age <37 gestational weeks) and 48 (51.07%) were mature babies (>37 gestational weeks). Pregnancies conceived by IVF in 74% of the cases were delivered by a cesarean section.

Conclusion
Assisted reproductive techniques have been used more often now compared to 10 years ago. These days we face with many elderly patients, aged above 35 years, conceived by in vitro fertilization and embryo transfer. Perinatal outcomes and mode of delivery in this group of patients stays debatable. After analyzing the maternal and gestational age, also the parity, we concluded that singleton pregnancies conceived by IVF are no benefit for delivery by a cesarean section.
